

ISTQL 2012 Summer School - Spatial Statistics and Econometrics

Şebnem Er, Neslihan Fidan

July 3-14, 2012

1 INTRODUCTION TO R AND PRELIMINARIES

- What is R?
 - Executing Commands from an External File
 - Object Oriented R
 - How to Set your Working Directory
 - Getting Help
- Simple Manipulations, numbers and vectors
 - Vectors and Assignment
 - Writing a Sequence
 - Vector Arithmetic
- Other types of objects
 - Other Types of Objects
 - Arrays and Matrices
 - Lists and Data Frames
- Graphical Displays
 - Boxplots
 - Multiple Boxplots
 - Histograms
 - Scatter Plots

2 SPATIAL DATA AND ANALYSIS OF SPATIAL DATA

- What is a Spatial Data
- Spatial Data Sets
 - Data Available in the Packages
 - Ways to Import Spatial Data
 - Ways to Visualise Spatial Data
- Analysing Spatial Data
 - Measures of Spatial Dependence
 - Creating Neighbours and Connectivity (Weights') Matrix
 - Non-Spatial Tests for OLS Residuals
 - Spatial Tests for OLS Residuals
 - Spatial Lag Model - SAR
 - Spatial Lag Model - SAR - ML
 - Spatial Lag Model - SAR - Mixed
 - Spatial Lag Model - SAR - IV
 - Spatial Error Model - SE
 - Spatial Error Model - SE - ML
 - Spatial Error Model - SE - GMM
 - SARAR - ML
 - SARAR - GMM
 - Boston Data Set
 - Dealing with Heteroskedasticity in Spatial Models
- Spatial Panel Models

2 SPATIAL DATA AND ANALYSIS OF SPATIAL DATA

- Spatial Panel Models

What is R?

- R was created by Ross Ihaka and Robert Gentleman at the University of Auckland.

What is R?

- R was created by Ross Ihaka and Robert Gentleman at the University of Auckland.
- R is named partly after the first names of the first two R authors (Robert Gentleman and Ross Ihaka), and partly as a play on the name of S, the famous statistical programming language.

What is R?

- R was created by Ross Ihaka and Robert Gentleman at the University of Auckland.
- R is named partly after the first names of the first two R authors (Robert Gentleman and Ross Ihaka), and partly as a play on the name of S, the famous statistical programming language.
- R is an integrated suite of software facilities for data manipulation and analysis, calculation and graphical display.

What is R?

- R was created by Ross Ihaka and Robert Gentleman at the University of Auckland.
- R is named partly after the first names of the first two R authors (Robert Gentleman and Ross Ihaka), and partly as a play on the name of S, the famous statistical programming language.
- R is an integrated suite of software facilities for data manipulation and analysis, calculation and graphical display.
- R is a free software.
- R is very much a vehicle for newly developing methods of interactive data analysis. It has developed rapidly, and has been extended by a large collection of packages.

Using R

- Technically R is an expression language with a very simple syntax, and R uses a command line interface; however, several graphical user interfaces are available for use with R.

Using R

- Technically R is an expression language with a very simple syntax, and R uses a command line interface; however, several graphical user interfaces are available for use with R.
- R is CASE SENSITIVE as are most UNIX based packages, so A and a are different symbols and would refer to different variables.

Using R

- Technically R is an expression language with a very simple syntax, and R uses a command line interface; however, several graphical user interfaces are available for use with R.
- R is CASE SENSITIVE as are most UNIX based packages, so A and a are different symbols and would refer to different variables.
- R is also a calculator.

Using R

- Technically R is an expression language with a very simple syntax, and R uses a command line interface; however, several graphical user interfaces are available for use with R.
- R is CASE SENSITIVE as are most UNIX based packages, so A and a are different symbols and would refer to different variables.
- R is also a calculator.
- Elementary commands in R consist of either expressions or assignments. If an expression is given as a command, it is evaluated, printed (unless specifically made invisible), and the value is lost. An assignment also evaluates an expression and passes the value to a variable but the result is not automatically printed.

Using R

- Technically R is an expression language with a very simple syntax, and R uses a command line interface; however, several graphical user interfaces are available for use with R.
- R is CASE SENSITIVE as are most UNIX based packages, so A and a are different symbols and would refer to different variables.
- R is also a calculator.
- Elementary commands in R consist of either expressions or assignments. If an expression is given as a command, it is evaluated, printed (unless specifically made invisible), and the value is lost. An assignment also evaluates an expression and passes the value to a variable but the result is not automatically printed.
- R provides a mechanism for recalling and re-executing previous commands. The vertical arrow keys on the keyboard can be used to scroll forward and backward through a command history.

Executing Commands from an External File

You can either use the R Console or write your scripts in an R file.
That way you can keep your codes and run them the next time you open R.

```
> source("week1day1.R")
```

Object Oriented R

The entities that R creates and manipulates are known as objects. These may be variables, arrays of numbers, character strings, functions, or more general structures built from such components. During an R session, objects are created and stored by name. The R command:

```
> objects()
```

Alternatively, `ls()` can be used to display the names of (most of) the objects which are currently stored within R. The collection of objects currently stored is called the workspace.

Object Oriented R

All objects created during an R session can be stored permanently in a file for use in future R sessions. At the end of each R session you are given the opportunity to save all the currently available objects. If you indicate that you want to do this, the objects are written to a file called `‘.Rdata’` in the current directory, and the command lines used in the session are saved to a file called `‘.Rhistory’`.

Object Oriented R

All objects created during an R session can be stored permanently in a file for use in future R sessions. At the end of each R session you are given the opportunity to save all the currently available objects. If you indicate that you want to do this, the objects are written to a file called `‘.Rdata’` in the current directory, and the command lines used in the session are saved to a file called `‘.Rhistory’`.

When R is started at later time from the same directory it reloads the workspace from this file. At the same time the associated commands history is reloaded. It is recommended that you should use separate working directories for analyses conducted with R. It is quite common for objects with names `x` and `y` to be created during an analysis.

How to Set your Working Directory

Workspace: All objects created in R are stored in workspace (using backward slash twice)

How to Set your Working Directory

Workspace: All objects created in R are stored in workspace (using backward slash twice)

```
> setwd("C:\\Users\\TOSHIBA\\Downloads\\Spatial\\AnilBERA\\latexpdf")
```

How to Set your Working Directory

Workspace: All objects created in R are stored in workspace (using backward slash twice)

```
> setwd("C:\\Users\\TOSHIBA\\Downloads\\Spatial\\AnilBERA\\latexpdf")
```

or equivalently (using forward slash only for once)

How to Set your Working Directory

Workspace: All objects created in R are stored in workspace (using backward slash twice)

```
> setwd("C:\\Users\\TOSHIBA\\Downloads\\Spatial\\AnilBERA\\latexpdf")
```

or equivalently (using forward slash only for once)

```
> setwd("C:/Users/TOSHIBA/Downloads/Spatial/AnilBERA/latexpdf")
```

How to Set your Working Directory

Workspace: All objects created in R are stored in workspace (using backward slash twice)

```
> setwd("C:\\Users\\TOSHIBA\\Downloads\\Spatial\\AnilBERA\\latexpdf")
```

or equivalently (using forward slash only for once)

```
> setwd("C:/Users/TOSHIBA/Downloads/Spatial/AnilBERA/latexpdf")
```

in order to see which directory is assigned:

```
> getwd()
```

```
[1] "C:/Users/TOSHIBA/Downloads/Spatial/AnilBERA/latexpdf"
```

Getting Help

```
> help()
> help.start()
> help(mean)
> ?mean
> demo()
> ?read.table
> help.search ("data.entry")
> apropos (boxplot)
```

2 SPATIAL DATA AND ANALYSIS OF SPATIAL DATA

- Spatial Panel Models

Vectors and Assignment

R operates on named data structures. The simplest such structure is the numeric vector, which is a single entity consisting of an ordered collection of numbers. To set up a vector named `y`, say, consisting of five numbers, namely 10.4, 5.6, 3.1, 6.4 and 21.7, use the R command:

```
> y <- c(10.4, 5.6, 3.1, 6.4, 21.7)
```

Vectors and Assignment

R operates on named data structures. The simplest such structure is the numeric vector, which is a single entity consisting of an ordered collection of numbers. To set up a vector named `y`, say, consisting of five numbers, namely 10.4, 5.6, 3.1, 6.4 and 21.7, use the R command:

```
> y <- c(10.4, 5.6, 3.1, 6.4, 21.7)
```

This is an assignment statement using the function `c()` which in this context can take an arbitrary number of vector arguments and whose value is a vector got by concatenating its arguments end to end. A number occurring by itself in an expression is taken as a vector of length one.

Vectors and Assignment

Notice that the assignment operator ('<-'), which consists of the two characters '<' ("less than") and '-' ("minus") occurring strictly side-by-side and it 'points' to the object receiving the value of the expression. In most contexts the '=' operator can be used as an alternative.

```
> y = c(10.4, 5.6, 3.1, 6.4, 21.7)
```

Vectors and Assignment

Notice that the assignment operator ('<-'), which consists of the two characters '<' ("less than") and '-' ("minus") occurring strictly side-by-side and it 'points' to the object receiving the value of the expression. In most contexts the '=' operator can be used as an alternative.

```
> y = c(10.4, 5.6, 3.1, 6.4, 21.7)
```

```
> x <- 1:10
```

```
> y <- x + rnorm(10,0,1)
```

```
> x+y
```

```
[1] 3.079802 3.065141 6.812409 7.005371 10.215046 11.775668  
[7] 13.738748 17.274728 18.373461 18.107064
```

Writing a Sequence

```
> x = 1:4
```

```
> x
```

```
[1] 1 2 3 4
```

Writing a Sequence

```
> x = 1:4
```

```
> x
```

```
[1] 1 2 3 4
```

```
> xsquare = x**2
```

```
> xsquare
```

```
[1] 1 4 9 16
```

Writing a Sequence

```
> x = 1:4
```

```
> x
```

```
[1] 1 2 3 4
```

```
> xsquare = x**2
```

```
> xsquare
```

```
[1] 1 4 9 16
```

```
> prod1 = x*10
```

```
> prod1
```

```
[1] 10 20 30 40
```

Writing a Sequence

The function `seq()` is a more general facility for generating sequences. It has five arguments, only some of which may be specified in any one call. The first two arguments, if given, specify the beginning and end of the sequence, and if these are the only two arguments given the result is the same as the colon operator.

```
> seq(-5, 5, by=.2) -> s3
```

generates in `s3` the vector `c(-5.0, -4.8, -4.6, ..., 4.6, 4.8, 5.0)`.

Writing a Sequence

The function `seq()` is a more general facility for generating sequences. It has five arguments, only some of which may be specified in any one call. The first two arguments, if given, specify the beginning and end of the sequence, and if these are the only two arguments given the result is the same as the colon operator.

```
> seq(-5, 5, by=.2) -> s3
```

generates in `s3` the vector `c(-5.0, -4.8, -4.6, ..., 4.6, 4.8, 5.0)`.

Similarly,

Writing a Sequence

The function `seq()` is a more general facility for generating sequences. It has five arguments, only some of which may be specified in any one call. The first two arguments, if given, specify the beginning and end of the sequence, and if these are the only two arguments given the result is the same as the colon operator.

```
> seq(-5, 5, by=.2) -> s3
```

generates in `s3` the vector `c(-5.0, -4.8, -4.6, ..., 4.6, 4.8, 5.0)`.

Similarly,

```
> s4 <- seq(length=51, from=-5, by=.2)
```

generates the same vector in `s4`.

More on Vectors

Remember the vector y ?

```
> y = c(10.4, 5.6, 3.1, 6.4, 21.7)
```

More on Vectors

Remember the vector y ?

```
> y = c(10.4, 5.6, 3.1, 6.4, 21.7)
```

Let's say you need to know the length of the vector to write a for loop.

```
> length(y)
```

```
[1] 5
```

More on Vectors

Remember the vector y ?

```
> y = c(10.4, 5.6, 3.1, 6.4, 21.7)
```

Let's say you need to know the length of the vector to write a for loop.

```
> length(y)
```

```
[1] 5
```

To concatenate vectors

```
> z<-cbind(x,y) # combines x and y by columns
```

```
> v<-rbind(x,y) # by rows
```

More on Vectors

Remember the vector y ?

```
> y = c(10.4, 5.6, 3.1, 6.4, 21.7)
```

Let's say you need to know the length of the vector to write a for loop.

```
> length(y)
```

```
[1] 5
```

To concatenate vectors

```
> z<-cbind(x,y) # combines x and y by columns
```

```
> v<-rbind(x,y) # by rows
```

To learn the dimensions

```
> dim(z) # 3 rows 2 columns
```

```
[1] 5 2
```

```
> dim(v)
```

```
[1] 2 5
```

```
> length(z) # number of elements
```

```
[1] 10
```

Vector arithmetic

Vectors can be used in arithmetic expressions, in which case the operations are performed element by element. The elementary arithmetic operators are the usual $+$, $-$, $*$, $/$ and a^{\wedge} for raising to a power. In addition all of the common arithmetic functions are available. \log , \exp , \sin , \cos , \tan , $\sqrt{\quad}$, and so on, all have their usual meaning:

- Spatial Panel Models

Other types of objects

Vectors are the most important type of object in R, but there are several others.

- matrices or more generally arrays are multi-dimensional generalizations of vectors. In fact, they are vectors that can be indexed by two or more indices and will be printed in special ways.

Other types of objects

Vectors are the most important type of object in R, but there are several others.

- matrices or more generally arrays are multi-dimensional generalizations of vectors. In fact, they are vectors that can be indexed by two or more indices and will be printed in special ways.
- factors provide compact ways to handle categorical data.

Other types of objects

Vectors are the most important type of object in R, but there are several others.

- matrices or more generally arrays are multi-dimensional generalizations of vectors. In fact, they are vectors that can be indexed by two or more indices and will be printed in special ways.
- factors provide compact ways to handle categorical data.
- lists are a general form of vector in which the various elements need not be of the same type, and are often themselves vectors or lists. Lists provide a convenient way to return the results of a statistical computation.

Other types of objects

Vectors are the most important type of object in R, but there are several others.

- factors provide compact ways to handle categorical data.
- lists are a general form of vector in which the various elements need not be of the same type, and are often themselves vectors or lists. Lists provide a convenient way to return the results of a statistical computation.
- data frames are matrix-like structures, in which the columns can be of different types. Think of data frames as 'data matrices' with one row per observational unit but with (possibly) both numerical and categorical variables. Many experiments are best described by data frames: the treatments are categorical but the response is numeric.

Other types of objects

Think of data frames as 'data matrices' with one row per observational unit but with (possibly) both numerical and categorical variables. Many experiments are best described by data frames: the treatments are categorical but the response is numeric.
- functions are themselves objects in R which can be stored in the project's workspace.

Create a New Matrix

A matrix is the special case of a two-dimensional array with the following syntax:

```
matrix(data,nrow,ncol,byrow)
```

Create a New Matrix

A matrix is the special case of a two-dimensional array with the following syntax:

```
matrix(data,nrow,ncol,byrow)
```

Let's start with a vector of size 12:

```
> a<-c(2,-2,9,3,1,4,5,4,0,1,4,-3)
```

Create a New Matrix

A matrix is the special case of a two-dimensional array with the following syntax:

```
matrix(data,nrow,ncol,byrow)
```

Let's start with a vector of size 12:

```
> a<-c(2,-2,9,3,1,4,5,4,0,1,4,-3)
```

If you want to transform this vector into a 3X4 matrix:

```
> A<- matrix(a, nrow=3,ncol=4) # creates a matrix based on columns (default).
> A
```

```
      [,1] [,2] [,3] [,4]
[1,]    2    3    5    1
[2,]   -2    1    4    4
[3,]    9    4    0   -3
```

If you want you can create a matrix by rows with the `byrow=TRUE` option.

```
> length(a) # dim(a)-> NULL
[1] 12
> dim(A)
[1] 3 4
> nrow(A)
[1] 3
> ncol(A)
[1] 4
> length(A) # number of the elements in A matrix
[1] 12
```

```
> length(a) # dim(a)-> NULL
[1] 12

> dim(A)
[1] 3 4

> nrow(A)
[1] 3

> ncol(A)
[1] 4

> length(A) # number of the elements in A matrix
[1] 12
```

If you will need to work with the elements of a matrix

```
> A[3,]
[1] 9 4 0 -3
```

```
> A[3,2]
[1] 4
```

```
> length(a) # dim(a)-> NULL
```

```
[1] 12
```

```
> dim(A)
```

```
[1] 3 4
```

```
> nrow(A)
```

```
[1] 3
```

```
> ncol(A)
```

```
[1] 4
```

```
> length(A) # number of the elements in A matrix
```

```
[1] 12
```

If you will need to work with the elements of a matrix

```
> A[3,]
```

```
[1] 9 4 0 -3
```

```
> A[3,2]
```

```
[1] 4
```

```
> A[,3]
```

```
[1] 5 4 0
```

```
> A[1]
```

```
[1] 2
```

```
> A[1:3,2] # 1,2,3rd rows on second column.
```

```
[1] 3 1 4
```

```
> A[c(1,3),] # first and third rows and all the
```

```
      [,1] [,2] [,3] [,4]
[1,]    2    3    5    1
[2,]    9    4    0   -3
```

```
> A[c(1,3),2]
```

```
[1] 3 4
```

Diagonal Matrix and Type of Objects

To obtain the diagonal elements of
a matrix

```
> diag(A)
```

```
[1] 2 1 0
```

Diagonal Matrix and Type of Objects

To obtain the diagonal elements of
a matrix

```
> diag(A)
```

```
[1] 2 1 0
```

To learn the object's type use class function:

```
> class(A) # matrix
```

```
[1] "matrix"
```

```
> class(a) # numeric (vector)
```

```
[1] "numeric"
```

```
> class(A[1,]) # numeric (vector)
```

```
[1] "numeric"
```

Unit Matrix

How do you think you would generate a Unit Matrix?

Unit Matrix

How do you think you would generate a Unit Matrix?

```
> I<-diag(1,nrow=3,ncol=3) # 3-by-3
> zeros <- matrix(0,nrow=3,ncol=3) # all the elements equal to zero
> ones <- matrix(1,nrow=3,ncol=3) # all the elements equal to 1
> I<- matrix(0,nrow=3,ncol=3) #preparing unit matrix
> I[row(I)==col(I)] <- 1 # diagonal elements equal 1
> I
```

```
      [,1] [,2] [,3]
[1,]    1    0    0
[2,]    0    1    0
[3,]    0    0    1
```

Matrix Operations

Let's create another matrix called B:

```
> b<-c(0,-1,-4,0,3,4,7,2,-3,10,4,8)
```

```
> B<- matrix(b, nrow=3,ncol=4)
```

```
> B
```

```
      [,1] [,2] [,3] [,4]
[1,]    0    0    7   10
[2,]   -1    3    2    4
[3,]   -4    4   -3    8
```

Matrix Operations

Let's create another matrix called B:

```
> b<-c(0,-1,-4,0,3,4,7,2,-3,10,4,8)
> B<- matrix(b, nrow=3,ncol=4)
> B
```

```
      [,1] [,2] [,3] [,4]
[1,]    0    0    7   10
[2,]   -1    3    2    4
[3,]   -4    4   -3    8
```

Summation/subtraction of two matrices:

```
> C<-A+B # remember A and B should have same dimension
> Y<-A-B
```

Matrix Operations

Let's create another matrix called B:

```
> b<-c(0,-1,-4,0,3,4,7,2,-3,10,4,8)
> B<- matrix(b, nrow=3,ncol=4)
> B
```

```
      [,1] [,2] [,3] [,4]
[1,]    0    0    7   10
[2,]   -1    3    2    4
[3,]   -4    4   -3    8
```

Summation/subtraction of two matrices:

```
> C<-A+B # remember A and B should have same dimension
> Y<-A-B
```

Using a scalar:

```
> C5<-5*A # (or C5<-A*5 same)
> Cp5<-A+3
```

Product of two matrices ($m \times n$ & $n \times k$)

```
> dim(A)
```

```
[1] 3 4
```

```
> dim(B)
```

```
[1] 3 4
```

Product of two matrices (mxn & nxk)

```
> dim(A)
```

```
[1] 3 4
```

```
> dim(B)
```

```
[1] 3 4
```

Since both A and B are 3X4, we need the transpose of A or B to be able to multiply A and B.

```
> t(A) # transpose of matrix A
```

```
      [,1] [,2] [,3]
[1,]    2   -2    9
[2,]    3    1    4
[3,]    5    4    0
[4,]    1    4   -3
```

```
> dim(t(A))
```

```
[1] 4 3
```

```
> P<-A%*%t(B) # (3x3)
```

```
> P4<-t(A)%*%B # (4x4)
```

Inverse of a Matrix - Square Matrix

```
> D<-matrix(c(2,4,5,3,-1,7,-3,5,-2),nrow=3,ncol=3)
> Di<-solve(D)
> round(Di%%D) # should yield unit matrix
```

```
      [,1] [,2] [,3]
[1,]    1    0    0
[2,]    0    1    0
[3,]    0    0    1
```

```
> Di
```

```
      [,1]      [,2]      [,3]
[1,]  0.5  0.22727273 -0.1818182
[2,] -0.5 -0.16666667  0.3333333
[3,] -0.5 -0.01515152  0.2121212
```

Cholesky Decomposition

Knowing that

- A is square matrix and positive definite
- $A=LL^* L$, lower triangular

The Cholesky decomposition is mainly used for the numerical solution of linear equations $Ax = b$. If A is symmetric and positive definite, then we can solve $Ax = b$ by first computing the Cholesky decomposition $A = LL'$, then solving $Ly = b$ for y , and finally solving $L'x = y$ for x .

```
> T=matrix(c(1,1,1,1,5,5,1,5,14),nrow=3)
> chol(T)
```

```
      [,1] [,2] [,3]
[1,]    1    1    1
[2,]    0    2    2
[3,]    0    0    3
```

Lists and Data Frames

Data Entry: Entering data from a file to a data frame

Lists and Data Frames

Data Entry: Entering data from a file to a data frame

```
> boston.c =read.table("C:/data/bostondata.csv",header=T,sep=",")
```

Lists and Data Frames

Data Entry: Entering data from a file to a data frame

```
> boston.c = read.table("C:/data/bostondata.csv", header=T, sep=",")
```

if you don't want to write the directory each time you can specify a folder in a specific directory and assign this directory as your work place, remember `setwd()`?

Lists and Data Frames

Data Entry: Entering data from a file to a data frame

```
> boston.c = read.table("C:/data/bostondata.csv", header=T, sep=",")
```

if you don't want to write the directory each time you can specify a folder in a specific directory and assign this directory as your work place, remember `setwd()`?

```
> boston.c = read.table("bostondata.csv", header=T, sep=",")
```

The file name must be always written in quotes:

What is a Spatial Data

All spatial data consist of positional information, answering the question 'where is it?'. (Bivand, et al., 2008, pp.8)

What is a Spatial Data

All spatial data consist of positional information, answering the question 'where is it?'. (Bivand, et al., 2008, pp.8)

The different types of data models that are distinguished in R include the following: (Bivand, et al., 2008, pp.8)

What is a Spatial Data

All spatial data consist of positional information, answering the question 'where is it?'. (Bivand, et al., 2008, pp.8)

The different types of data models that are distinguished in R include the following: (Bivand, et al., 2008, pp.8)

1 Continuous data (surfaces)

2 Discrete data

- Point, a single point location, such as a GPS reading or a geocoded address
- Line, a set of ordered points, connected by straight line segments
- Polygon (regular-irregular), an area, marked by one or more enclosing lines, possibly containing holes. A polygon is formed when a set of line segments forms a closed object with no lines intersecting.
- Grid, a collection of points or rectangular cells, organised in a regular lattice

What is a Spatial Data

All spatial data consist of positional information, answering the question 'where is it?'. (Bivand, et all., 2008, pp.8)

The different types of data models that are distinguished in R include the following: (Bivand, et all., 2008, pp.8)

1 Continuous data (surfaces)

2 Discrete data

- Point, a single point location, such as a GPS reading or a geocoded address
- Line, a set of ordered points, connected by straight line segments
- Polygon (regular-irregular), an area, marked by one or more enclosing lines, possibly containing holes. A polygon is formed when a set of line segments forms a closed object with no lines intersecting.
- Grid, a collection of points or rectangular cells, organised in a regular lattice

Spatial data are usually displayed on maps, where the x- and y-axes show the coordinate values, with the aspect ratio chosen such that a unit in x equals a unit in y. (Bivand, et all., 2008)

R and Spatial Objects

Every object in R is of a particular class. You have seen numeric, vector, matrix and data.frame classes. To learn the type of the object type in R:

```
> x=c(1,2,3,5)
> class(x)
[1] "numeric"
```

R and Spatial Objects

Every object in R is of a particular class. You have seen numeric, vector, matrix and data.frame classes. To learn the type of the object type in R:

```
> x=c(1,2,3,5)
> class(x)
[1] "numeric"
```

In R, for spatial data, the foundation class is the Spatial class, with just two slots. The first is a bounding box, a matrix of numerical coordinates with column names c(min,max), and at least two rows, with the first row eastings (x-axis) and the second northings (y-axis). The second is a CRS class object defining the coordinate reference system. (Bivand, et al., 2008, pp.28)

R and Spatial Objects

Every object in R is of a particular class. You have seen numeric, vector, matrix and data.frame classes. To learn the type of the object type in R:

```
> x=c(1,2,3,5)
> class(x)
[1] "numeric"
```

In R, for spatial data, the foundation class is the Spatial class, with just two slots. The first is a bounding box, a matrix of numerical coordinates with column names c(min,max), and at least two rows, with the first row eastings (x-axis) and the second northings (y-axis). The second is a CRS class object defining the coordinate reference system. (Bivand, et al., 2008, pp.28)

Start R and load the packages spdep and splancs.

Class "SpatialGridDataFrame", by class "SpatialGrid", distance 2
Class "SpatialLinesDataFrame", by class "SpatialLines", distance 2
```

R and Spatial Objects

Most of the data used in economic research are irregular aeral data and generally consist of regional aggregates, which are administratively and politically defined. These can be cities, provinces, states, regions etc. Data belonging to such regional form are stored in a shapefile, which are produced by GIS.

R and Spatial Objects

Most of the data used in economic research are irregular aeral data and generally consist of regional aggregates, which are administratively and politically defined. These can be cities, provinces, states, regions etc. Data belonging to such regional form are stored in a shapefile, which are produced by GIS.

A shapefile consists of at least 3 files with extensions of .shp, .dbf, .shx. Using the readShapePoly function in R, it is easy to import, store and visualise a shapefile. Using the object created after importing the shapefile into R, spatial analysis can be used via the package spdep.

Example Data Sets that will be Used

Throughout the tutorials we will be using the famous Boston house price data, Columbus crime data, EU regional data collected at the NUTS2 level.

- Boston data: contains the classic Harrison and Rubinfeld (1978) housing data set with observations on 23 variables for 506 census tracts.

Example Data Sets that will be Used

Throughout the tutorials we will be using the famous Boston house price data, Columbus crime data, EU regional data collected at the NUTS2 level.

- Boston data: contains the classic Harrison and Rubinfeld (1978) housing data set with observations on 23 variables for 506 census tracts.
- Columbus data: <http://www.neighborhoodscout.com/oh/columbus/crime/>

Example Data Sets that will be Used

Throughout the tutorials we will be using the famous Boston house price data, Columbus crime data, EU regional data collected at the NUTS2 level.

- Boston data: contains the classic Harrison and Rubinfeld (1978) housing data set with observations on 23 variables for 506 census tracts.
- Columbus data: <http://www.neighborhoodscout.com/oh/columbus/crime/>
- EU2 Data: There are three levels of Nomenclature of Territorial Units for Statistics (NUTS) defined. This category refers to regions belonging to the second level (NUTS 2, also known as NUTS II), which is largely used by Eurostat and other European Union bodies.

Example Data Sets that will be Used

Throughout the tutorials we will be using the famous Boston house price data, Columbus crime data, EU regional data collected at the NUTS2 level.

- Boston data: contains the classic Harrison and Rubinfeld (1978) housing data set with observations on 23 variables for 506 census tracts.
- Columbus data: <http://www.neighborhoodscout.com/oh/columbus/crime/>
- EU2 Data: There are three levels of Nomenclature of Territorial Units for Statistics (NUTS) defined. This category refers to regions belonging to the second level (NUTS 2, also known as NUTS II), which is largely used by Eurostat and other European Union bodies.

Any spatial data set includes the geometric characteristics of the spatial units which are spatial coordinates, index of the geometries, the attributes associated to each spatial unit. These can be any economic, social data.

Any spatial data set includes the geometric characteristics of the spatial units which are spatial coordinates, index of the geometries, the attributes associated to each spatial unit. These can be any economic, social data.

The datasets are available from:

<http://www.isletme.istanbul.edu.tr/ogrelem/sebnemer/spatial/>

Columbus Data Set I

Now let's go to the datasets available in `spdep` R package, specifically Columbus data. To do that type in R:

```
> example(columbus)
```

```
colmbs> columbus <- readShapePoly(system.file("etc/shapes/columbus.shp",  
colmbs+ package="spdep")[1])
```

```
colmbs> col.gal.nb <- read.gal(system.file("etc/weights/columbus.gal",  
colmbs+ package="spdep")[1])
```

A major pleasure in working with spatial data is their visualisation. Maps are amongst the most compelling graphics. Let's plot the regions:

```
> plot(columbus)
```

To see the spread of CRIME among the regions:

```
> brks <- round(quantile(columbus$CRIME), digits=4)
> colours <- heat.colors(length(brks))
> plot(columbus, col=colours[findInterval(columbus$CRIME,
+ brks,all.inside=TRUE)])
> legend(x="topright", legend=leglabs(brks),fill=colours,
+ bty="n", cex=0.6)
> title(main="Crime level in Columbus (1980)",cex=.4)
```

Crime level in Columbus (1980)

How to Import Spatial Data

To import the shapefile for EU at the NUTS2 level, we will use the `readShapePoly` function as follows:

How to Import Spatial Data

To import the shapefile for EU at the NUTS2 level, we will use the `readShapePoly` function as follows: Assuming that the EU2 spatial data files are in your working directory:

```
> EU2=readShapePoly("EU2",IDvar="Id")  
> getinfo.shape("EU2.shp")
```

Shapefile type: Polygon, (5), # of Shapes: 190

```
> names(EU2)
```

```
[1] "SP_ID"      "Id"         "Name"       "gprb"  
[5] "lninv1b"   "pr80b"     "pr103b"    "lndens_emp"  
[9] "lndens_pop" "lnagrib"
```

How to Import Spatial Data

To import the shapefile for EU at the NUTS2 level, we will use the `readShapePoly` function as follows: Assuming that the EU2 spatial data files are in your working directory:

```
> EU2=readShapePoly("EU2",IDvar="Id")  
> getinfo.shape("EU2.shp")
```

Shapefile type: Polygon, (5), # of Shapes: 190

```
> names(EU2)
```

```
[1] "SP_ID"      "Id"         "Name"       "gprb"  
[5] "lninv1b"   "pr80b"      "pr103b"     "lndens_emp"  
[9] "lndens_pop" "lnagrib"
```

You may want to update this data with other variables included in the text file. Firstly, read in the text file into R.

How to Import Spatial Data

To import the shapefile for EU at the NUTS2 level, we will use the `readShapePoly` function as follows: Assuming that the EU2 spatial data files are in your working directory:

```
> EU2=readShapePoly("EU2",IDvar="Id")
> getinfo.shape("EU2.shp")
```

Shapefile type: Polygon, (5), # of Shapes: 190

```
> names(EU2)
```

```
[1] "SP_ID"      "Id"         "Name"       "gprb"
[5] "lninv1b"   "pr80b"     "pr103b"    "lndens_emp"
[9] "lndens_pop" "lnagrib"
```

You may want to update this data with other variables included in the text file. Firstly, read in the text file into R.

```
> EU_updated=read.table("EU_updated.txt",header=T)
> names(EU_updated)
```

```
[1] "Codes"      "Pop1990"   "Pop1991"   "Pop1992"   "Pop1993"   "Pop1994"
[7] "Pop1995"   "Pop1996"   "Pop1997"   "Pop1998"   "Pop1999"   "Pop2000"
[13] "Pop2001"   "Pop2002"   "Pop2003"   "Pop2004"   "Pop2005"   "Pop2006"
[19] "Pop2007"   "Pop2008"   "Pop2009"   "Pop2010"   "Pop2011"   "GDP1995"
[25] "GDP1996"   "GDP1997"   "GDP1998"   "GDP1999"   "GDP2000"   "GDP2001"
[31] "GDP2002"   "GDP2003"   "GDP2004"   "GDP2005"   "GDP2006"   "GDP2007"
[37] "GDP2008"   "GDP2009"
```

How to Import Spatial Data

Then, merge the shapefile and the dataframe using the merge function according to the columns of Id in the EU2 shapefile and the Codes in the newEU dataframe.

```
> newEU=merge(EU2, EU_updated, by.x="Id", by.y="Codes")
> names(newEU)
```

[1]	"Id"	"SP_ID"	"Name"	"gprb"
[5]	"lninv1b"	"pr80b"	"pr103b"	"lndens_emp"
[9]	"lndens_pop"	"lnagrib"	"Pop1990"	"Pop1991"
[13]	"Pop1992"	"Pop1993"	"Pop1994"	"Pop1995"
[17]	"Pop1996"	"Pop1997"	"Pop1998"	"Pop1999"
[21]	"Pop2000"	"Pop2001"	"Pop2002"	"Pop2003"
[25]	"Pop2004"	"Pop2005"	"Pop2006"	"Pop2007"
[29]	"Pop2008"	"Pop2009"	"Pop2010"	"Pop2011"
[33]	"GDP1995"	"GDP1996"	"GDP1997"	"GDP1998"
[37]	"GDP1999"	"GDP2000"	"GDP2001"	"GDP2002"
[41]	"GDP2003"	"GDP2004"	"GDP2005"	"GDP2006"
[45]	"GDP2007"	"GDP2008"	"GDP2009"	

How to Visualise Spatial Data

Let us plot the EU2 shapefile.

```
> plot(EU2)
```

How to Visualise Spatial Data

If you want to see the names of the NUTS2 levels then use the following:

```
> plot(EU2)
> text(coordinates(EU2), labels=sapply(slot(EU2, "polygons"),
+ function(i) slot(i, "ID")), cex=0.1, col="blue")
```

How to Visualise Spatial Data

Now let's calculate the quartiles for the GDP per capita in 2009.

```
> brks <- round(quantile(newEU$GDP2009), digits=4)
```

To give a grey scaled colour to each quartile, use the following:

```
> colours <- grey((length(brks):2)/length(brks))
```

How to Visualise Spatial Data

To plot these colours on the map, type the following:

```
> plot(EU2, col=colours[findInterval(newEU$GDP2009, brks,all.inside=TRUE)])  
> legend(x="bottomright", legend=leglabs(brks),fill=colours, bty="n", cex=0.4)  
> title(main="EU NUTS2 Level GDP per capita (in Euros) - 2009", cex=0.3)
```

EU NUTS2 Level GDP per capita (in Euros) – 2009

Tobler's first law of geography:

“Everything is related to everything else, but close things are more related than things that are far apart.”

Tobler's first law of geography:

“Everything is related to everything else, but close things are more related than things that are far apart.”

From this definition, we need to identify who are the neighbours of each unit and what is the strength of their relationship. In order to do that for each unit we need a list of neighbours and spatial weights.

Creating Neighbours and Connectivity (Weights') Matrix

In order to analyse a spatial dataset, firstly, we need to do two things:

- 1 Defining spatial neighbours
- 2 Creating spatial weights' matrices

Defining Spatial Neighbours

Neighbourhood relationship can be defined in different ways: (Arbia, 2005, pp.37)

1 Contiguity-based neighbourhood:

In the case of discrete-parameter random fields, a simple definition of neighbourhood could be based on the mere adjacency between 2 polygons. In this case two polygons indexed by S_i and S_j are said to be neighbours if they share a common boundary.

This can be in the 3 different form:

- Rook
- Bishop
- Queen

Defining Spatial Neighbours

Neighbourhood relationship can be defined in different ways: (Arbia, 2005, pp.37)

1 Contiguity-based neighbourhood:

In the case of discrete-parameter random fields, a simple definition of neighbourhood could be based on the mere adjacency between 2 polygons. In this case two polygons indexed by S_i and S_j are said to be neighbours if they share a common boundary.

This can be in the 3 different form:

- Rook
- Bishop
- Queen

2 K-nearest neighbourhood

Two sites S_i and S_j are said to be neighbours if $d_{ij} = \text{Min}(d_{ik}) \forall i, k$.

Defining Spatial Neighbours

Neighbourhood relationship can be defined in different ways: (Arbia, 2005, pp.37)

1 Contiguity-based neighbourhood:

In the case of discrete-parameter random fields, a simple definition of neighbourhood could be based on the mere adjacency between 2 polygons. In this case two polygons indexed by S_i and S_j are said to be neighbours if they share a common boundary.

This can be in the 3 different form:

- Rook
- Bishop
- Queen

2 K-nearest neighbourhood

Two sites S_i and S_j are said to be neighbours if $d_{ij} = \text{Min}(d_{ik}) \forall i, k$.

3 Critical cut-off neighbourhood

Two sites S_i and S_j are said to be neighbours if $0 \leq d_{ij} < d^*$, with d_{ij} the appropriate distance adopted, and d^* representing a critical cut-off.

Neighbours in R - Contiguity-based neighbourhood:

Neighbours are stored as an “nb” class. Very easy to remember nb:neighurburs. In R:

Neighbours in R - Contiguity-based neighbourhood:

Neighbours are stored as an “nb” class. Very easy to remember `nb:neighbours`. In R:

```
> contnb_queen=poly2nb(columbus,queen=TRUE)
> contnb_queen[1]
```

```
[[1]]
[1] 2 3
```

```
> summary(contnb_queen)
```

Neighbour list object:

Number of regions: 49

Number of nonzero links: 236

Percentage nonzero weights: 9.829238

Average number of links: 4.816327

Link number distribution:

```
 2  3  4  5  6  7  8  9 10
 5  9 12  5  9  3  4  1  1
```

5 least connected regions:

0 5 41 45 46 with 2 links

1 most connected region:

19 with 10 links

```
> coords=coordinates(columbus) # to be able to see the centroid
> # of each polygon
```

Neighbours in R

Let's say we want to see on the plot who is the neighbour of who:

```
> plot(columbus) # plots a simple map
```

```
> plot(contnb_queen,coords,add=TRUE) # adds lines of connectivity according to the c
```

Neighbours in R - K-nearest neighbourhood

There are 2 steps to be followed:

1 Firstly, we need to define the k nearest neighbours:

2 Secondly, we need to create the nb class of neighbours using the `knn2nb()`.

```
> whoisthefirstnear=knearneigh(coords,k=1,longlat=TRUE)
```

```
> knn1columbus=knn2nb(whoisthefirstnear)
```

Neighbours in R - K-nearest neighbourhood

There are 2 steps to be followed:

- 1 Firstly, we need to define the k nearest neighbours:
- 2 Secondly, we need to create the nb class of neighbours using the `knn2nb()`.

```
> whoisthefirstnear=knearneigh(coords,k=1,longlat=TRUE)
```

```
> knn1columbus=knn2nb(whoisthefirstnear)
```

If you want to plot the new neighbours on the plot simply repeat what you have done previously.

```
> plot(columbus) # plots a simple map
```

```
> plot(knn1columbus,coords,add=TRUE) # adds lines of connectivity according to the 1st nearest nb
```

Neighbours in R - Critical cut-off neighbourhood

In order to define the neighbours within a distance we need that distance measure. It is called a threshold.

Neighbours in R - Critical cut-off neighbourhood

In order to define the neighbours within a distance we need that distance measure. It is called a threshold. To calculate the threshold, we will use a function called `nbdisks()` to calculate the distances between the centroids of the polygons. Let's say we base our calculations according to the 1st nearest neighbours.

Neighbours in R - Critical cut-off neighbourhood

In order to define the neighbours within a distance we need that distance measure. It is called a threshold. To calculate the threshold, we will use a function called `nbdist()` to calculate the distances between the centroids of the polygons. Let's say we base our calculations according to the 1st nearest neighbours.

```
> distBetwNeigh1=nbdist(knn1columbus,coords,longlat=TRUE)
> all.linkedTresh=max(unlist(distBetwNeigh1))
> all.linkedTresh

[1] 67.48852
```

Neighbours in R - Critical cut-off neighbourhood

In order to define the neighbours within a distance we need that distance measure. It is called a threshold. To calculate the threshold, we will use a function called `nbdists()` to calculate the distances between the centroids of the polygons. Let's say we base our calculations according to the 1st nearest neighbours.

```
> distBetwNeigh1=nbdists(knn1columbus,coords,longlat=TRUE)
> all.linkedTresh=max(unlist(distBetwNeigh1))
> all.linkedTresh

[1] 67.48852

> dnbTresh1=dnearneigh(coords,0,68,longlat=TRUE)
> summary(dnbTresh1)
```

Neighbour list object:

Number of regions: 49

Number of nonzero links: 252

Percentage nonzero weights: 10.49563

Average number of links: 5.142857

Link number distribution:

```
 1  2  3  4  5  6  7  8  9 10 11
4  8  6  2  5  8  6  2  6  1  1
```

4 least connected regions:

6 10 21 47 with 1 link

1 most connected region:

28 with 11 links

Neighbours in R

If you want to plot the new neighbours on the plot simply repeat what you have done previously.

```
> plot(columbus) # plots a simple map
```

```
> plot(dnbTresh1,coords,add=TRUE) # adds lines of connectivity according to the 1st
```

Neighbours in R

If you want to plot the new neighbours on the plot simply repeat what you have done previously.

```
> plot(columbus) # plots a simple map
```

```
> plot(dnbTresh1,coords,add=TRUE) # adds lines of connectivity according to the 1st
```

Neighbours in R

You can plot the 3 neighbourhood definitions side-by-side. Remember `par()`?

```
> par(mfrow = c(1,3))
> plot(columbus)
> plot(contnb_queen, coords, add=TRUE)
> plot(columbus)
> plot(knn1columbus, coords, add=TRUE)
> plot(columbus)
> plot(dnbTresh1, coords, add=TRUE)
```

Defining Weights

We use `nb2listw()` to create the weights.

Let's say we are gonna create the weights' matrix according to the first type of neighbourhood relationship, contiguity based.

Defining Weights

We use `nb2listw()` to create the weights.

Let's say we are gonna create the weights' matrix according to the first type of neighbourhood relationship, contiguity based.

```
> contnb_queen.listw=nb2listw(contnb_queen,style="W",zero.policy=FALSE)
```

```
> class(contnb_queen.listw)
```

```
[1] "listw" "nb"
```

```
> contnb_queen[1] # polygon indices of the 1st one.
```

```
[[1]]
```

```
[1] 2 3
```

```
> contnb_queen.listw$weights[1]
```

```
[[1]]
```

```
[1] 0.5 0.5
```

Defining Weights

We use `nb2listw()` to create the weights.

Let's say we are gonna create the weights' matrix according to the first type of neighbourhood relationship, contiguity based.

```
> contnb_queen.listw=nb2listw(contnb_queen,style="W",zero.policy=FALSE)
```

```
> class(contnb_queen.listw)
```

```
[1] "listw" "nb"
```

```
> contnb_queen[1] # polygon indices of the 1st one.
```

```
[[1]]
```

```
[1] 2 3
```

```
> contnb_queen.listw$weights[1]
```

```
[[1]]
```

```
[1] 0.5 0.5
```

Now you can try to understand the others.

Morans I

Let's continue with the contiguity based neighbourhood definition:

```
> moran.test(columbus$CRIME, contnb_queen.listw)
```

Morans I test under randomisation

```
data: columbus$CRIME
```

```
weights: contnb_queen.listw
```

```
Moran I statistic standard deviate = 5.5894, p-value =
1.139e-08
```

```
alternative hypothesis: greater
```

```
sample estimates:
```

Moran I statistic	Expectation	Variance
0.500188557	-0.020833333	0.008689289

Please calculate the Morans I according to the other neighbourhood relationships.

Having your Own Spatial Weights Matrix in a File

In most cases, we have a `data.frame` and a weights matrix that is prepared by using other kinds of neighbourhood relationships rather than the ones based on distances.

Having your Own Spatial Weights Matrix in a File

In most cases, we have a `data.frame` and a weights matrix that is prepared by using other kinds of neighbourhood relationships rather than the ones based on distances.

In that case, you have 2 files:

- 1 Your `data.frame`
- 2 Your weights matrix

Having your Own Spatial Weights Matrix in a File

In most cases, we have a `data.frame` and a weights matrix that is prepared by using other kinds of neighbourhood relationships rather than the ones based on distances.

In that case, you have 2 files:

- 1 Your `data.frame`
- 2 Your weights matrix

Firstly, you need to upload them into R and then do a few manipulations in the weights' matrix. Then, you can do any kind of analysis.

Now let's see how to do this:

Having your Own Spatial Weights Matrix in a File

In most cases, we have a data.frame and a weights matrix that is prepared by using other kinds of neighbourhood relationships rather than the ones based on distances.

In that case, you have 2 files:

- 1 Your data.frame
- 2 Your weights matrix

Firstly, you need to upload them into R and then do a few manipulations in the weights' matrix. Then, you can do any kind of analysis.

Now let's see how to do this:

```
> gdpTR12region=read.table("turkey12regionsGDP2001.txt", header=TRUE)
> TR12regionWM=as.matrix(read.table("turkey12regionsWeightsMatrix.txt"))
> weights.listw=mat2listw(TR12regionWM, style="W")
> weights.listw$weights[1] #for Istanbul
```

```
[[1]]
[1] 0.2 0.2 0.2 0.2 0.2
```

```
> moran.test(gdpTR12region$GDPindollars2001,weights.listw)
```

Morans I test under randomisation

```
data: gdpTR12region$GDPindollars2001
weights: weights.listw
```

```
Moran I statistic standard deviate = 3.9918, p-value =
3.279e-05
```

```
alternative hypothesis: greater
```

```
sample estimates:
```

Moran I statistic	Expectation	Variance
0.51524743	-0.09090909	0.02305872

OLS vs Spatial Analysis

If you do OLS to a dataset that has spatial dependence, then you are in trouble. To see if your OLS residuals have a spatial dependence you can simply run an OLS and obtain the residuals and test your residuals with Morans I test.

```
> OLScolumbus=lm(CRIME~INC+HOVAL, data=columbus)
> plot(residuals(OLScolumbus))
> moran.test(residuals(OLScolumbus),contnb_queen.listw)
```

Morans I test under randomisation

```
data: residuals(OLScolumbus)
weights: contnb_queen.listw
```

```
Moran I statistic standard deviate = 2.6521, p-value =
0.003999
```

```
alternative hypothesis: greater
```

```
sample estimates:
```

Moran I statistic	Expectation	Variance
0.222109407	-0.020833333	0.008391173

OLS vs Spatial Analysis

To apply the Morans I test in the OLS residuals use the function `lm.morantest()`.

```
> OLScolumbus=lm(CRIME~INC+HOVAL, data=columbus)
> lm.morantest(OLScolumbus, contnb_queen.listw, resfun=rstudent)
```

Global Morans I for regression residuals

```
data:
model: lm(formula = CRIME ~ INC + HOVAL, data = columbus)
weights: contnb_queen.listw
```

Moran I statistic standard deviate = 2.355, p-value = 0.009262

alternative hypothesis: greater

sample estimates:

Observed Morans I	Expectation	Variance
0.178520703	-0.033418335	0.008099305

OLS vs Spatial Analysis

To apply the Morans I test in the OLS residuals use the function `lm.morantest()`.

```
> OLScolumbus=lm(CRIME~INC+HOVAL, data=columbus)
> lm.morantest(OLScolumbus, contnb_queen.listw, resfun=rstudent)
```

Global Morans I for regression residuals

```
data:
model: lm(formula = CRIME ~ INC + HOVAL, data = columbus)
weights: contnb_queen.listw
```

Moran I statistic standard deviate = 2.355, p-value =
0.009262

alternative hypothesis: greater

sample estimates:

Observed Morans I	Expectation	Variance
0.178520703	-0.033418335	0.008099305

Since Morans I test is based on the assumption of normality, we'd better check if the residuals have a normal distribution or not.

Non-Spatial Tests for OLS Residuals

In order to run the non-spatial tests for OLS residuals, you need 2 packages:

```
> library(lmtest)
> library(tseries)
```

Heteroscedasticity Tests

```
> BP<-bptest(OLScolumbus, studentize=FALSE)
> BP
```

Breusch-Pagan test

```
data: OLScolumbus
BP = 10.0128, df = 2, p-value = 0.006695
```

```
> BP<-bptest(OLScolumbus, studentize=TRUE)
> BP
```

studentized Breusch-Pagan test

```
data: OLScolumbus
BP = 7.2166, df = 2, p-value = 0.0271
```

Results show that OLS residuals are heteroscedastic

Normality Tests and Plots

Jarque-Bera Normality Test, Not Jarque-Beta!!!

Normality Tests and Plots

Jarque-Bera Normality Test, Not Jarque-Beta!!!

```
> JB<-jarque.bera.test(residuals(OLScolumbus))  
> JB
```

Jarque Bera Test

```
data: residuals(OLScolumbus)  
X-squared = 1.8358, df = 2, p-value = 0.3994
```

Normality Tests and Plots

Jarque-Bera Normality Test, Not Jarque-Beta!!!

```
> JB<-jarque.bera.test(residuals(OLScolumbus))  
> JB
```

Jarque Bera Test

```
data: residuals(OLScolumbus)  
X-squared = 1.8358, df = 2, p-value = 0.3994
```

To plot the residuals:

Normality Tests and Plots

Estimating Spatial Correlation: Variogram

In geostatistics the spatial correlation is modelled by the variogram instead of a correlogram or covariogram. The variogram plots semivariance as a function of distance. (Bivand, et al., pp.195)

A simple way to acknowledge that spatial correlation is present or not is to make scatter plots of pairs $Z(s_i)$ and $Z(s_j)$, grouped according to their separation distance $h_{ij} = \|s_i - s_j\|$. The empirical semivariance is described by

$$\hat{\gamma}(h) = \frac{1}{2} \frac{1}{n_h} \sum_{i=1}^{n(h)} (z(s_i + h) - z(s_i))^2$$

Plotting Variogram

```
> library(gstat)
> data(columbus)
> # convert simple data frame into a spatial data frame object:
> coordinates(columbus) <- ~ X+Y
> variog1 <- variogram(CRIME~1, columbus)
> plot(variog1) # See 14 points
```

Plotting Variogram

For the interval width, `gstat` uses a default of the cutoff value divided by 15. Choosing a smaller interval width will result in more detail, as more estimates of (h) appear. The distance vector does not have to be cut in regular intervals, `boundaries=c(0,50,100,seq(250,1500,250))`

```
> variog2 <- variogram(CRIME~1, boundaries=0:100, data=columbus)
> # boundaries; number of points
> plot(variog2)
```

Plotting Variogram

```
> model.variog <- vgm(psill=200, model="Exp", range=5)  
> fit.variog <- fit.variogram(variog1, model.variog)  
> plot(variog1, model=fit.variog)
```

Plotting Variogram

The following parameters are often used to describe variograms:

- **nugget** : The height of the jump of the semivariogram at the discontinuity at the origin.
- **sill** : Limit of the variogram tending to infinity lag distances.
- **range** : The distance in which the difference of the variogram from the sill becomes negligible. In models with a fixed sill, it is the distance at which this is first reached; for models with an asymptotic sill, it is conventionally taken to be the distance when the semivariance first reaches 95 % of the sill..

$\text{psill} = 350 - 50 \cdot 50$

Model options are: exponential, spherical, Gaussian and Matern For weighted least squares fitting a variogram model to the sample variogram (Cressie, 1985), we need to take several steps:

- 1** Choose a suitable model (such as exponential, ...), with or without nugget
- 2** Choose suitable initial values for partial sill(s), range(s), and possibly nugget
- 3** Fit this model, using one of the fitting criteria.

Fit ranges and/or sills from a simple or nested variogram model to a sample variogram

Boston Data Set and the Variables

The original data are 506 observations on 14 variables, medv being the target variable.

crim	per capita crime rate by town
zn	proportion of residential land zoned for lots over 25,000 sq.ft
indus	proportion of non-retail business acres per town
chas	Charles River dummy variable (= 1 if tract bounds river; 0 otherwise)
nox	nitric oxides concentration (parts per 10 million)
rm	average number of rooms per dwelling
age	proportion of owner-occupied units built prior to 1940
dis	weighted distances to five Boston employment centres
rad	index of accessibility to radial highways
tax	full-value property-tax rate per USD 10,000
ptratio	pupil-teacher ratio by town
b	$1000(B - 0.63)^2$ where B is the proportion of blacks by town
lstat	percentage of lower status of the population
medv	median value of owner-occupied homes in USD 1000's

■ Spatial Panel Models

Getting into Panel Models: Fixed vs Random

Consider a linear panel model:

$$y_{it} = X_{it}\beta + u_{it} \quad (1)$$

Here the error term u_{it} is our concern.

If we believe that the unobservable factors effect the i th value of y in time t then we have to deal with that.

Most of the panel data applications assume that the composite error term u_{it} follows a one-way error structure,

$$u_{it} = \mu_i + \epsilon_{it}$$

that has two components, μ_i specific to countries that does not change over time and ϵ_{it} that changes both over time and for countries.

Getting into Panel Models: Fixed vs Random

Consider a linear panel model:

$$y_{it} = X_{it}\beta + u_{it} \quad (1)$$

Here the error term u_{it} is our concern.

If we believe that the unobservable factors effect the i th value of y in time t then we have to deal with that.

Most of the panel data applications assume that the composite error term u_{it} follows a one-way error structure,

$$u_{it} = \mu_i + \epsilon_{it}$$

that has two components, μ_i specific to countries that does not change over time and ϵ_{it} that changes both over time and for countries.

In order to find if the spatial specific effects (μ_i) are significant and therefore the estimation of the model with the pooled Ordinary Least Squares (OLS) estimates would be biased and inconsistent, joint significance of the country specific factors with F-test should be applied.

Getting into Panel Models: Fixed vs Random

- This test basically compares the sum square errors of the fixed effects and OLS methods, and if a significant F is obtained then the test reveals that the country specific effects are significant (Baltagi, 2011).

Getting into Panel Models: Fixed vs Random

- This test basically compares the sum square errors of the fixed effects and OLS methods, and if a significant F is obtained then the test reveals that the country specific effects are significant (Baltagi, 2011).
- Though at this point, another concern arises on how to treat these effects. Since it is found that there are unobserved country specific factors which causes the error to be autocorrelated, the estimation of (1) by the ordinary least squares becomes impossible (Wooldridge, 2002).

Getting into Panel Models: Fixed vs Random

- This test basically compares the sum square errors of the fixed effects and OLS methods, and if a significant F is obtained then the test reveals that the country specific effects are significant (Baltagi, 2011).
- Though at this point, another concern arises on how to treat these effects. Since it is found that there are unobserved country specific factors which causes the error to be autocorrelated, the estimation of (1) by the ordinary least squares becomes impossible (Wooldridge, 2002).
- Therefore there are methods developed for panel data. These methods analyse the u_{it} composite error term by assuming that the one-way error structure is either fixed or random (Frees, 2004, Wooldridge, 2002).

Getting into Panel Models: Fixed vs Random

- This test basically compares the sum square errors of the fixed effects and OLS methods, and if a significant F is obtained then the test reveals that the country specific effects are significant (Baltagi, 2011).
- Though at this point, another concern arises on how to treat these effects. Since it is found that there are unobserved country specific factors which causes the error to be autocorrelated, the estimation of (1) by the ordinary least squares becomes impossible (Wooldridge, 2002).
- Therefore there are methods developed for panel data. These methods analyse the u_{it} composite error term by assuming that the one-way error structure is either fixed or random (Frees, 2004, Wooldridge, 2002).
- The decision on which method to use is the most important thing in panel data analysis (Matyas, Sevestre, 1996) and it depends on the existence of correlation between the explanatory variables and the unobservable cross sectional specific factors (Arellano, 2003, Wooldridge, 2002). There is no restriction about zero correlation between the explanatory variables and the unobservable cross sectional specific factors (μ_i) in the fixed effects models. However, random effects estimates are based on zero correlation assumption. As a result, if the correlations between the explanatory variables and the unobservable cross sectional specific factors (μ_i) are found to be high then one should hesitate in estimating the panel data with random effects since the basic assumption would be violated.

Getting into Panel Models: Fixed vs Random

- There is also a Hausman test that compares the less efficient fixed effects model with the more efficient random effects model under the null of no significant difference. The test tries to find if the more efficient random effects model also gives consistent results and if the null is not rejected then the more efficient random effects model is preferred.

Getting into Panel Models: Fixed vs Random

- There is also a Hausman test that compares the less efficient fixed effects model with the more efficient random effects model under the null of no significant difference. The test tries to find if the more efficient random effects model also gives consistent results and if the null is not rejected then the more efficient random effects model is preferred.
- On the other hand, if the test finds that there is significant difference between the models, then it is more appropriate to use fixed effects models. Though it has to be kept in mind that Hausman test is not a test to make a choice between fixed or random. There is more to be kept in mind. If the data set includes all of the cross-sectional units rather than a randomly chosen sample from the large population, it is more appropriate to obtain the fixed effects model estimates.

Getting into Panel Models: Fixed vs Random

- There is also a Hausman test that compares the less efficient fixed effects model with the more efficient random effects model under the null of no significant difference. The test tries to find if the more efficient random effects model also gives consistent results and if the null is not rejected then the more efficient random effects model is preferred.
- On the other hand, if the test finds that there is significant difference between the models, then it is more appropriate to use fixed effects models. Though it has to be kept in mind that Hausman test is not a test to make a choice between fixed or random. There is more to be kept in mind. If the data set includes all of the cross-sectional units rather than a randomly chosen sample from the large population, it is more appropriate to obtain the fixed effects model estimates.
- Once it is decided to estimate a fixed effects model, it means that μ_i is assumed to be fixed parameters to be estimated and therefore least squares dummy variable estimation approach or within group transformations are applied, whereas if it is decided for a random effects model, then μ_i is assumed to be a random component and generalized least squares estimation approach is applied which is nothing more than applying OLS to the transformed variables with the inverse of the variance-covariance matrix of the composite error terms (Baltagi, 2001, Bhargava, Franzini & Narendranathan, 1982).

Tests in Panel Data Analysis

1 Tests of poolability

tests the hypothesis that the same coefficients apply to each individual. It is a standard F test, based on the comparison of a model obtained for the full sample and a model based on the estimation of an equation for each individual.

Tests in Panel Data Analysis

1 Tests of poolability

tests the hypothesis that the same coefficients apply to each individual. It is a standard F test, based on the comparison of a model obtained for the full sample and a model based on the estimation of an equation for each individual.

2 Tests for individual and time effects

This is Lagrange multiplier tests of individual or/and time effects based on the results of the pooling model.

Tests in Panel Data Analysis

1 Tests of poolability

tests the hypothesis that the same coefficients apply to each individual. It is a standard F test, based on the comparison of a model obtained for the full sample and a model based on the estimation of an equation for each individual.

2 Tests for individual and time effects

This is Lagrange multiplier tests of individual or/and time effects based on the results of the pooling model.

3 Hausman test

Hausman test which is based on the comparison of two sets of estimates (see Hausman 1978). A classical application of the Hausman test for panel data is to compare the fixed and the random effects models.

Tests in Panel Data Analysis

1 Tests of poolability

Hausman test which is based on the comparison of two sets of estimates (see Hausman 1978). A classical application of the Hausman test for panel data is to compare the fixed and the random effects models.

4 Tests for cross-sectional dependence

Panel Estimation in R: Fixed vs Random

We will use `plm` package in developed by Croissant and Millo.

```
> library(plm)
```

Panel Estimation in R: Fixed vs Random

We will use `plm` package in developed by Croissant and Millo.

```
> library(plm)
```

`plm` provides four functions for estimation:

- `plm`: estimation of the basic panel models, i.e., within, between and random effect models. Models are estimated using the `lm` function to transformed data,
- `pvcmm`: estimation of models with variable coefficients,

```
> data(Grunfeld)
```

```
> fm <- inv ~ value + capital
```

Panel Estimation in R: Fixed vs Random

```

```
> fm <- inv ~ value + capital
```

A `panelmodel` object contains:

coefficients, residuals, fitted.values, vcov, df.residual and call.

Panel Estimation in R: Fixed vs Random

Several models can be estimated with `plm` by changing the model argument:

- the fixed effects model (within),

Panel Estimation in R: Fixed vs Random

Several models can be estimated with `plm` by adding the `model` argument:

- the fixed effects model (`within`),
- the pooling model (`pooling`),

Panel Estimation in R: Fixed vs Random

Several models can be estimated with `plm` by using the `model` argument:

- the fixed effects model (`within`),
- the pooling model (`pooling`),
- the first-difference model (`fd`),

Panel Estimation in R: Fixed vs Random

Several models can be estimated with `plm` by using the `model` argument:

- the fixed effects model (`within`),
- the pooling model (`pooling`),
- the first-difference model (`fd`),
- the between model (`between`),

Panel Estimation in R: Fixed vs Random

Several models can be estimated with `plm` by using the `model` argument:

- the fixed effects model (`within`),
- the pooling model (`pooling`),
- the first-difference model (`fd`),
- the between model (`between`),
- the error components model (`random`).

Grunfeld data: Fixed Effects

For fixed effects:

```
> grun.fe <- plm(fm, data = Grunfeld, model = "within")
```

Grunfeld data: Fixed Effects

For fixed effects:

```
> grun.fe <- plm(fm, data = Grunfeld, model = "within")
```

Fixed effects may be extracted easily using `fixef` function:

```
> fixef(grun.fe)
```

1	2	3	4	5
-70.296717	101.905814	-235.571841	-27.809295	-114.616813
6	7	8	9	10
-23.161295	-66.553474	-57.545657	-87.222272	-6.567844

And you can summarize the fixed effects:

```
> summary(fixef(grun.fe))
```

	Estimate	Std. Error	t-value	Pr(> t)
1	-70.2967	49.7080	-1.4142	0.15730

Grunfeld data: Random Effects

For random effects:

```
> grun.re <- plm(fm, data = Grunfeld, model = "random")
```

Grunfeld data: Random Effects

For random effects:

```
> grun.re <- plm(fm, data = Grunfeld, model = "random")
```

The random effect model is obtained as a linear estimation on quasidemeaned data. The parameter of this transformation is obtained using preliminary estimations. Four estimators of this parameter are available, depending on the value of the argument `random.method`: `swar`, `walhus`, `amemiya`, `nerlove`. Default is `swar`.

Grunfeld data: Random Effects

For random effects:

```
> grun.re <- plm(fm, data = Grunfeld, model = "random")
```

The random effect model is obtained as a linear estimation on quasidemeaned data. The parameter of this transformation is obtained using preliminary estimations. Four estimators of this parameter are available, depending on the value of the argument `random.method`: `swar`, `walhus`, `amemiya`, `nerlove`. Default is `swar`.

```
> grun.re <- plm(fm, data = Grunfeld, model = "random", random.method="amemiya")
```

Grunfeld data: Two-Way Effects - both individual and time effects

If you want to estimate a time-effect model, then use the effect option:

Grunfeld data: Two-Way Effects - both individual and time effects

If you want to estimate a time-effect model, then use the effect option:

```
> grun.time<- plm(fm, data = Grunfeld, effect="time", model = "random",  
+ random.method="amemiya")
```

Grunfeld data: Two-Way Effects - both individual and time effects

If you want to estimate a time-effect model, then use the effect option:

```
> grun.time<- plm(fm, data = Grunfeld, effect="time", model = "random",  
+ random.method="amemiya")
```

If you want both effects:

```
> grun.twoways<- plm(fm, data = Grunfeld, effect="twoways", model = "random",  
+ random.method="amemiya")
```

```

```
alternative hypothesis: unstability
```

Grunfeld data - Tests: Individual and Time Effects

`plmtest` implements Lagrange multiplier tests of individual or/and time effects based on the results of the pooling model. Its main argument is a `plm` object (the result of a pooling model) or a formula.

Grunfeld data - Tests: Individual and Time Effects

`plmtest` implements Lagrange multiplier tests of individual or/and time effects based on the results of the pooling model. Its main argument is a `plm` object (the result of a pooling model) or a formula.

The effects tested are indicated with the `effect` argument (one of individual, time or twoways). To test for the presence of both individual and time effects:

```
> g <- plm(fm, data = Grunfeld, model = "pooling")
> plmtest(g, effect = "twoways", type = "ghm")
```

Lagrange Multiplier Test - two-ways effects (Gourieroux, Holly and Monfort)

```
data: fm
chisq = 798.1615, df = 2, p-value < 2.2e-16
alternative hypothesis: significant effects
```

Grunfeld data - Tests: Individual and Time Effects

pFtest computes F tests of effects based on the comparison of the within and the pooling models. Its main arguments are either two plm objects (the results of a pooling and a within model) or a formula.

Grunfeld data - Tests: Individual and Time Effects

pFtest computes F tests of effects based on the comparison of the within and the pooling models. Its main arguments are either two plm objects (the results of a pooling and a within model) or a formula.

```
> gw <- plm(fm, data = Grunfeld, effect = "twoways", model = "within")
> gp <- plm(fm, data = Grunfeld, model = "pooling")
> pFtest(gw, gp)
```

F test for twoways effects

data: fm

F = 17.4031, df1 = 28, df2 = 169, p-value < 2.2e-16

> phtest(gw, gr)
```

Hausman Test

```
data: inv ~ value + capital
chisq = 2.3304, df = 2, p-value = 0.3119
alternative hypothesis: one model is inconsistent
```

Spatial Panel Estimation

The spatial lag model (SAR) posits that the dependent variable depends on the dependent variable observed in neighbouring units and on a set of observed local characteristics.

$$Y_{it} = \rho \sum_{j=1}^N w_{ij} y_{jt} + \mathbf{x}_{it} \boldsymbol{\beta} + \mu_i + \epsilon_{it} \quad (2)$$

Spatial Panel Estimation

The spatial lag model (SAR) posits that the dependent variable depends on the dependent variable observed in neighbouring units and on a set of observed local characteristics.

$$Y_{it} = \rho \sum_{j=1}^N w_{ij} y_{jt} + \mathbf{x}_{it} \boldsymbol{\beta} + \mu_i + \epsilon_{it} \quad (2)$$

The spatial error model (SEM), on the other hand, posits that the dependent variable depends on a set of observed local characteristics and that the error terms are correlated across space

$$Y_{it} = \mathbf{x}_{it} \boldsymbol{\beta} + \mu_i + \epsilon_{it} \quad (3)$$

$$\epsilon_{it} = \lambda \sum_{j=1}^N w_{ij} \epsilon_{jt} + \nu_{it} \quad (4)$$

Here the spatial specific effects (μ_i) are approached as fixed or random.

Spatial Panel Estimation - Fixed Effect Spatial Lag

According to Anselin et al. (2006), the extension of the fixed effects model with a spatially lagged dependent variable raises two complications. First, the endogeneity of $\sum_j w_{ij}y_{jt}$ violates the assumption of the standard regression model that $E[(\sum_j w_{ij}y_{jt})\epsilon_{it}] = 0$. In model estimation, this simultaneity must be accounted for. Second, the spatial dependence among the observations at each point in time may affect the estimation of the fixed effects.

Spatial Panel Estimation - Fixed Effect Spatial Lag

According to Anselin et al. (2006), the extension of the fixed effects model with a spatially lagged dependent variable raises two complications. First, the endogeneity of $\sum_j w_{ij}y_{jt}$ violates the assumption of the standard regression model that $E[(\sum_j w_{ij}y_{jt})\epsilon_{it}] = 0$. In model estimation, this simultaneity must be accounted for. Second, the spatial dependence among the observations at each point in time may affect the estimation of the fixed effects.

Two main approaches have been suggested in the literature to estimate models that include spatial interaction effects. One is based on the maximum likelihood (ML) principle and the other on instrumental variables or generalized method of moments (IV/GMM) techniques.

Using splm - Munnell's productivity model

Munnell (1990), Public capital productivity: Does public capital (roads, water facilities, public buildings and structures) help growth? (Example 3 in Baltagi) 48 US states, annual data 1970-1986. Production function:

$$\log(gsp) = \alpha + \beta_1 \log(pcap) + \beta_2 \log(pc) + \beta_3 \log(emp) + \beta_4 unemp$$

```
> library(splm)
> data(Produc, package="Ecdat")
> data(usaww)
> fm <- log(gsp)~log(pcap)+log(pc)+log(emp)+unemp
```

Using `splm` - Munnell's productivity model

Munnell (1990), Public capital productivity: Does public capital (roads, water facilities, public buildings and structures) help growth? (Example 3 in Baltagi) 48 US states, annual data 1970-1986. Production function:

$$\log(gsp) = \alpha + \beta_1 \log(pcap) + \beta_2 \log(pc) + \beta_3 \log(emp) + \beta_4 unemp$$

```
> library(splm)
> data(Produc, package="Ecdat")
> data(usaww)
> fm <- log(gsp)~log(pcap)+log(pc)+log(emp)+unemp
```

Now check the `usaww` and `Produc...` The weights matrix should be a 48X48 matrix. Attention: It has already been row-standardized. You could have done it with the `mat2listw` function by setting the style to "w"

Create weights matrix

Since the weights matrix is in a matrix format, we have to transform it into a listw format.

Create weights matrix

Since the weights matrix is in a matrix format, we have to transform it into a listw format.

```
> usalw <- mat2listw(usaww)
```

Pooling SAR

Pooling SAR
