What is Social Network Analysis?

- \star A social network is defined as a network of interactions or relationships between actors.
- \star Social networks are mainly represented with a graph in which a set of vertices/nodes (actors) are connected to each other with edges representing some sort of a relationship (i.e. friendship, trade, flights etc.).
- \star Many different relationships can be represented with networks, i.e.
	- between friends representing friendship levels,
	- between academics representing collaboration levels,
	- between cities representing flight routes,
	- between companies representing trade,
	- between neurons in our brain representing neural connection etc.
- \star Social networks have become very popular in recent years.
- Online social networks

An analysis of corporate board networks in South Africa by Durbach, Parker 2009

In this paper we analyse the networks created from directors sitting on the boards of companies in South Africa. We consider two projections of this network: a director network, in which only directors are present and two directors are linked if they sit together on one or more common boards; and a firm network, in which only firms are present and an edge indicates that the two firms share one or more directors. We describe these networks in terms of the statistical properties that they possess, and compare them to theoretical values obtained under various random network models.

Who are the researchers that are collaborating with industry? An analysis of the wine sectors in Chile, South Africa and Italy by Giuliani, et.al, 2010

This paper provides new empirical evidence and, in particular, looks at the importance of researchers individual characteristics and their institutional environments in explaining the propensity to engage in different types of U-I linkages. Based on an original dataset, we present new evidence on three wine producing areas Piedmont, a region of Italy, Chile and South Africa that have successfully responded to recent structural changes in the industry worldwide. Empirical findings reveal that researchers individual characteristics, such as centrality in the academic system, age and sex, matter more than publishing records or formal degrees. Institutional specificities at country level also play a role in shaping the propensity of researchers to engage with industry.

Network data can be collected from either

- primary (we directly ask people questions or observe their behavior) or
- secondary (we gather data that already exists somewhere, whether in paper records, or electronic databases)

sources.

There is also increasing amount of longitudinal studies.

Types of Nodes and Edges

Most network studies involve persons as the nodes and interpersonal relations as the ties. However, the nodes can be all kinds of entities

- firms,
- cities,
- countries,
- monkeys.
- neurons,
- or even the characters in a book and so on.

And the type of node obviously has a major impact on what kinds of relationships are collected and how they are collected. These decisions are interlinked and must to some extent be considered together.

Sampling and Bounding

One of the most vexing problems for those just starting out in network research is the problem of bounding the set of nodes to be included in the study.

- Often the whole network is very large, and we only observe a portion of it.
- One needs to be careful because when you sample from the large network, the sub sample might not hold the original network properties.
- Sometimes a large network (ie. twitter) may be available but might be too complex.
- Sometimes we are interested in a rare feature of the observations, then random sampling is not efficient at all.

R [Packages](#page-83-0)

[Resources](#page-85-0)

Sampling and Bounding

There are two main sampling types to achieve these:

- induced subgraph sampling: sample vertices at random
- snowball sampling: interview any qualifying actor with a tie to any actor already selected, up to K waves or until quotas or cost limits reached.

Network Basics - Preliminaries

Graphs are commonly used to represent network data, and the graph shows the existence of some sort of a relationship between the individuals.

 $G = (V, E, W)$

is the mathematical form where $V = \{v_1, v_2, \ldots, v_n\}$ represents the set of vertices/nodes (individuals), and $E = \{e_1, e_2, \ldots, e_\ell\}$ represents the set of edges (interconnections between individuals/vertices), where W represents the edge weights, or in other words the strength of the connection. There are n vertices and L edges. In our friendship example, friend names are the vertices and the friendship levels are the edges.

Graphs can be either

- directed (digraph)
- undirected (no ordering of the vertices defining an edge)

Dr. \$ Er

Network Data Representation

Network Data can be represented in 2 ways:

- Edge list,
- Adjacency matrix.

Dr. S Er

[Outline](#page-1-0) [What is SNA?](#page-3-0) [Network Data](#page-4-0) [Preliminaries](#page-15-0) [Visualizing](#page-24-0) [Summarizing](#page-27-0) [Network](#page-45-0) Models [Mathematical](#page-46-0) Erdős Rényi [Small-World](#page-52-0) [Scale-Free](#page-59-0) [Comparison](#page-64-0) **[Statistical](#page-66-0)** [ERGM](#page-66-0)

R [Packages](#page-83-0)

[Resources](#page-85-0)

Simple example - Edge list with no information

2 column list, each row represents an edge between 2 nodes. All possible node points joined by an edge are represented by a list. Most common way of collecting data.

```
1 library ( igraph )
2 # example in data frame
3 a = c ( M^{\prime\prime}, "A", "A", "A", "A", "E", "F")
 4 b =c("B","C","D","E","F","F","G")
5 \text{ df} = \text{cbind}(a, b)6 df = as data frame (df)7 df
  > df
    a b
  1 A B
  2 A C
  3 A D
  4 A E
   5 A F
   6 E F
  7 F G
```
Dr. S Er

[Outline](#page-1-0) [What is SNA?](#page-3-0) [Network Data](#page-4-0) [Preliminaries](#page-15-0) [Visualizing](#page-24-0) [Summarizing](#page-27-0)

[Network](#page-45-0) Models

[Mathematical](#page-46-0) Erdős Rényi [Small-World](#page-52-0) [Scale-Free](#page-59-0) [Comparison](#page-64-0) **[Statistical](#page-66-0)** [ERGM](#page-66-0)

R [Packages](#page-83-0)

[Resources](#page-85-0)

Simple example - Adjacency matrix with no information

Represented in a matrix form $(N_V xN_V$ matrix) where the nodes are in the columns and rows of the matrix and the elements of the matrix are $0/1$ representing if a connection exists or not:

$$
A_{ij} = \begin{cases} 1, & \text{if } (i,j) \in E \\ 0, & \text{otherwise} \end{cases}
$$

When data is large, then very sparse and difficulties arise.

```
g = graph. edgelist (as. matrix (df [, 1:2]), directed =
    FALSE )
```

```
2 get. adjacency (g)
```

```
7 x 7 sparse Matrix of class "dgCMatrix"

Visualizing and Characterizing: Graph Layouts

Techniques for displaying network graphs are the focus of the field of graph drawing or graph visualization. Such techniques typically seek to incorporate a combination of elements from mathematics, human aesthetics, and algorithms. There are uncountably many ways.

Efficient algorithms have been developed and these can be called with the plot command in igraph package. At the heart of graph visualization is the graph layout, i.e., the placement of vertices and edges in space:

- circular layout,
- spring-embedder (pulling connected vertices closer to one another) methods: Fruchterman and Reingold layout
- grid layout,
- Kamada-Kawai algorithm,
- tree layout etc...

Visualizing - rules of thumb

Network graphics are easier to understand if they follow as much as possible the following five guidelines:

- Minimize edge crossings.
- Maximize the symmetry of the layout of nodes.
- Minimize the variability of the edge lengths.
- Maximize the angle between edges when they cross or join nodes.
- Minimize the total space used for the network display.

Descriptive Analysis: Nodal Degree

Nodal degree: Degree of a node is the number of edges which involve that node.

```
1 d.g = degree (g)2 d . g
3 vcount (g) # total number of vertices
 A B C D E F G
 5 1 1 1 2 3 1
```
there are seven vertices

For directed graphs, indegree-column sum, outdegree-row sum of the adjacency matrix.

• Mean nodal degree: a statistic that reports the average degree of nodes.

$$
\bar{d} = \frac{\sum_{i=1}^{g} d(v_i)}{g} = \frac{5+1+1+1+2+3+1}{7} = 2
$$

Descriptive Analysis: Nodal degree

• Variance of nodal degrees

$$
s_D^2 = \frac{\sum_{i=1}^g (d(v_i) - \bar{d})^2}{g}
$$

The nodal degrees are an important property of a graph, and we will often want to control for or condition on the set of nodal degrees in a graph when we use statistical models to study the tendencies towards higher order network properties.

For directed graphs, there are two measures: in-degree which is the column sum, and out-degree which is the row sum of the adjacency matrix.

Descriptive Analysis: Nodal degree

• Distribution of nodal degrees The distribution of nodal degrees (k different nodes) is represented with a probability distribution $P(k)$ defining the fraction of nodes with a particular degree level. Hence in our example there are 0 node with 0 edge, 4 nodes with 1 edge, 1 node with 2 edges, 1 node with 3

edges, 0 node with 4 edges and 1 node with 5 edges.

```
1 dd.g = degree.distribution(g)
2 dd.g; sum(dd.g); table(degree(g))/7
```
[1] 0.0000000 0.5714286 0.1428571 0.1428571 0.0000000 0.1428571 $[1] 1$ 1 2 3 5 0.5714286 0.1428571 0.1428571 0.1428571

Large majority of networks are right-skewed, more nodes with low degree, few nodes ("hubs") with high degree.

Descriptive Analysis: Nodal **Centrality**

Nodal Centrality: Vertex importance in the network. Which node is most central? Which actors in a social network seem to hold the 'reins of power'? There are a vast number of different centrality measures:

• Closeness centrality: An important vertex is central. Centrality is measured with the inverse of the total shortest path distance of a vertex from all others. The highest C_C measure tells us that node is tied with highest closeness.

$$
C_C(v_i) = \left[\sum_{j=1}^g d(v_i, v_j)\right]^{-1}
$$

[Resources](#page-85-0)

• Nodal Centrality

- Betweenness centrality: The importance of a vertex is related to where it is located with respect to the paths in the network graph.
- Connectivity: The smallest number of edges whose removal results in a disconnected graph.
- Spectral decomposition: Eigenvalues and eigenvectors of the adjacency matrix also provide another centrality measure.

Descriptive Analysis: Diameter

The diameter of a network is a useful measure of this compactness. A path is the series of steps required to go from node A to node B in a network.

The shortest path is the shortest number of steps required. The diameter then for an entire network is the longest of the shortest paths across all pairs of nodes. This is a measure of compactness or network efficiency in that the diameter reflects the 'worst case scenario' for sending information (or any other resource) across a network.

Although social networks can be very large, they can still have small diameters because of their density and clustering.

Descriptive Analysis: Network Cohesion

Network cohesion: The extent to which subsets of vertices are cohesive or 'stuck together' with respect to the relation defining edges in the network graph.

Cohesive subgroups are sets of actors that are tied together through frequent, strong, and direct ties.

Eg. Do friends of a given actor in a social network tend to be friends of one another as well?

There are many ways (i.e. subgraphs and censuses) that we can summarise network cohesion, we will focus on cliques and density.

• Cliques

Descriptive Analysis: Network cohesion

• Density of graphs: Ego-centric and Socio-centric. Degree is about the edges with each vertex in a graph. We can also consider the proportion of edges as a whole. The density of a graph is the proportion of possible edges that are actually present in the graph. It is the proportion of the number of edges present, L, to the maximum possible number of edges, denoted as Δ (for undirected graphs):

$$
\Delta = \frac{L}{n(n-1)/2}
$$

and $0 < \Delta < 1$

Descriptive Analysis: Local Clustering Coefficient

Eg. A has 5 connections, (B, C, D, E, F) and we are looking for which one of those connections are also connected. There are \mathcal{C}_2^5 possibilities that can happen: (B-C, B-D, B-E, B-F, C-D, C-E, C-F, D-E, D-F, E-F). Out of these 10 connections only 1 of them exists. Therefore the local clustering coefficient for A is 1/10. For C it is zero, doesn't even have two friends.

 $transitivity(g, type = "local")$

Descriptive Analysis: Global Clustering Coefficient

- The process of closure can be measured in a social network by examining its transitivity. Transitivity is defined as the proportion of closed triangles (triads where all three ties are observed) to the total number of open and closed triangles (triads where either two or all three ties are observed).
- Thus, like density, transitivity is a ratio that can range from 0 to 1 .

Network Models

So far we looked at the summary statistics such as density, centrality, transitivity etc.

With network models we can move beyond simple description to build and test hypotheses about network structures, formation processes, and network dynamics.

Several mathematical and statistical models have been proposed for this purpose. These provide insight into fundamental properties of social networks, serve as baseline or comparison models for empirical social networks, and act as building blocks for more complex network simulations.

Erdős Rényi Random Graph Model

The model is quite simple, $G(V, E)$, where a random graph G is defined with n vertices and L edges among those vertices chosen randomly. An equivalent model that is easier to work with is, where instead of specifying the number of edges, L, we define the probability, p, each edge appears in the graph.

```
1 op \leq par(mar=c(0,1,3,1), mfrow=c(2,2))
2 plot (erdos.renyi.game (n=12, 10, type='gnm'),

Erdős Rényi Random Graph Model

Properties of Erdős Rényi Random Graph Model:

• Number of edges:

$$
L=C_2^n x p
$$

• Average degree size:

$$
\bar{d}=(n-1)xp
$$

- For larger networks, one can also explore the degree distribution, and in fact the degree distribution follows a Poisson distribution (only for large networks!)
- Random graphs become entirely connected for fairly low values of average degree.

Erdős Rényi random graph model has one major limitation in that it does not describe the properties of many real-world social networks.

In particular, fully random graphs have degree distributions that do not match observed networks very well, and they also have quite low levels of clustering (transitivity).

Small-World Model

Steps of Small-World Models:

• The small-world model starts with a circle of nodes, where each node is connected to its c immediate neighbors (forming a formal lattice structure).

```
1 g = watts s strogatz q game (dim = 1, sig = 25, nei = 1, p)=0)
```

```
2 # 25^1 nodes , connected with 1 neighbour
```

```
3 # c=1 (1 path between two nodes along the
     circle )
```

```
4 # degree (g) will give us 2, each node has 2
     connections
```

```
5 g
6 plot(g)
```

```

Small-World Model

Steps of Small-World Models:

- Then, a small number of existing edges are rewired, where they are removed and then replaced with another tie that connects two random nodes. Number of edges do not change but links do change.
	- If the rewiring probability is 0, then we end up with the original lattice network (previous examples). 0 number of edges get rewired.
	- When p is 1, then we have an Erdős Rényi random graph. All of the edges get rewired.

The main interesting discovery of Watts and Strogatz (and others), is that only a small fraction of ties needs to be rewired to dramatically reduce the diameter of the network.

Small-World Model

The main interesting discovery of Watts and Strogatz (and others), is that only a small fraction of ties needs to be rewired to dramatically reduce the diameter of the network.

Fig. 10.6 Relationship of rewiring probability to network diameter for the small-world model

This plot is for 100 nodes. If we specify $c = 2$, we will have 200 edges. When we examine the relationship of rewiring probability (number of edges rewired/200) and the diameter of the network, we see that to reduce the diameter of the network, we just need to rewire 15 edges ($p = 15/200 = 0.075$).

Scale-Free Models

Previous two mathematical network models produce graphs with degree distributions that are not representative of many real-world social networks.

Numerous studies, in fact, have shown that a wide variety of observed networks have heavy-tailed degree distributions that approximately follow a power law distribution. These are typically called scale-free networks.

That is, as networks grow, new nodes are more likely to form ties with other nodes that already have many ties, due to their visibility in the network. This 'rich-gets-richer' phenomena has been shown to lead to the power-law distribution in networks.

One particular example of this type is World-Wide-Web.

Dr. S Er

[Outline](#page-1-0) [What is SNA?](#page-3-0) [Network Data](#page-4-0) [Preliminaries](#page-15-0) [Visualizing](#page-24-0) [Summarizing](#page-27-0) [Network](#page-45-0) Models [Mathematical](#page-46-0) Erdős Rényi

[Small-World](#page-52-0) [Scale-Free](#page-59-0) [Comparison](#page-64-0) **[Statistical](#page-66-0)** [ERGM](#page-66-0) R [Packages](#page-83-0)

[Resources](#page-85-0)

Scale-Free Models

Barabási and Albert (1999) discovered that World-Wide-Web had degree distribution of:

Prob(a random vertex has degree k) \sim Ck^{- γ}

for $k \to \infty$, C constant. This is called power-law behaviour and the γ is the power-law exponent.

The default behavior of the algorithm is that as each new node is added to the network, it is connected to another node in the network, with probability proportional to the degree of that node. Thus, some nodes in the network will end up with many more ties than most of the other nodes.

Comparing Random Models to Empirical Models

- By comparing the characteristics of the network models with the empirical network, we can highlight the interesting or important characteristics of the empirical network that might be worth further exploration by using, for example, the types of statistical modeling and simulation approaches.
- However, we need to remember that the observations are not independent!

- • ERGMs are generative statistical models of network structure and characteristics.
- Characteristics of the individual elements in the network (i.e., actors) and local structural properties can be used to predict properties of the entire network (e.g., diameter, degree distribution, etc.).
- ERGMs are flexible and can handle many different types of predictors and covariates, four broad categories:
	- node-level predictors,
	- dyadic predictors,
	- relational predictors, and
	- local structural predictors
- ERGMs are fit using Monte Carlo Markov Chain maximum-likelihood estimation (MCMC).
- ERGMs are implemented in the ergm package.

ERGM - Predictors

- The first type of predictor is node-level characteristics, where having a particular characteristic is hypothesized to affect the likelihood of observing a tie.
	- For example, if you hypothesize that girls are more likely to make friends than boys in middle school, then you could use actor gender as a node-level predictor.
- Dyad-level predictors are used when you hypothesize that the characteristics of both actors in a dyad may influence the probability of observing a tie between those two actors.
	- For example, if you think that friendships are more likely to be formed within the same grade in a middle school (assortative mixing), then you could use grade as a dyad-level predictor.
- The third type of predictor in ERGMs is a powerful option to use information about other relationships or ties when predicting the observed ties in a network.
	- That is, you can use one type of network tie to predict a second type of tie (as long as they are both collected on the same set of network members).
- Finally, information about local structural properties of the observed network can be used as model covariates.
	- This, for example, allows the network model to be conditioned on the observed degree distribution, or on the level of transitivity (closed triangles) that is observed.

Process of ERGMs

- Build ERGMs.
	- Build a null model no covariates, only edges,
	- Include node attributes.
	- Include dyadic predictors,
	- Include relational terms (network predictors),
	- Include local structural predictors (dyad dependency).
- Examine the build model.
	- Model interpretation,
	- Model fit,
	- Model diagnostics,
	- Simulating networks based on fit model.

ERGM example: UserNetR data

Network data that describe interorganizational relationships among 25 agencies within the Indiana state tobacco control program in 2010. These data include three different types of interorganizational ties: frequency of contact, level of collaboration, and whether each pair of agencies communicated with one another about a particular evidence-based guideline published by the Center's for Disease Control and Prevention (CDC), called Best Practices for Tobacco Control. This latter relationship is conceptualized as a type of dissemination tie.

ERGM: 2. Include node attributes - Model interpretation

- The number of years in tobacco control is positively and significantly associated with the likelihood of observing a tie between the two agencies.
- The effect of being the lead agency is is not significant. With only one lead agency in a small network of 25 members, there may not be the power to detect this effect.
- The AIC (Akaike information criterion) for this model with two predictors is lower than the AIC for the null model. This shows that this model is doing a better job of explaining the data than the baseline model.

ERGM: 3. Include dyadic predictors -

A rich source of hypotheses for network structures derive from questions about

- homophily (are ties more or less likely between network members who are similar to each other on some characteristic)
- heterophily (or dissimilar)

This is a type of dyadic interaction predictor, and ergm includes a number of these terms.

Dr. S Er

R [Packages](#page-83-0)

[Resources](#page-85-0)

ERGM: 3. Include dyadic predictors -

The raw frequencies of observed ties among and between different types of actors in the network can be displayed with the mixingmatrix() function.

```
1 TCnetworks $ TCdiss
2 mixingmatrix ( TCdiss ,'agency _lvl ')
```
Note: Marginal totals can be misleading for undirected mixing matrices. $2₂$ 1 13 24 14 2 24 16 23 3 14 23 13

Here, for example, we see that the most frequent dissemination ties (24) are observed between local and state-level agencies. It can be somewhat complicated to interpret these raw frequency patterns; however, they can generate hypotheses about dyadic interrelationships that can be formally tested in the ERGM.

ERGM: 3. Include dyadic predictors -

In the following models, the non-significant lead agency predictor is dropped. Three version of Model 2 are estimated, showing different options for including the dyadic comparison of agency level as a predictor.

```
1 DSmod2a \leq ergm (TCdiss edges + nodecov ('tob vrs')
      + nodematch ('agency_lvl'), control=control.
     ergm ( seed =40) )
```

```
3 DSmod2b <- ergm (TCdiss ~ edges + nodecov ('tob_yrs')
      + nodematch ('agency_lvl', diff=TRUE), control=
     control . ergm ( seed =40) )
```

```
5 DSmod2c <- ergm (TCdiss ~ edges + nodecov ('tob_yrs')
      + nodemix ('agency_lvl', base=1), control=
     control . ergm ( seed =40) )
```
ERGM: 3. Model2a

Model 2a uses the basic nodematch term to include one network predictor that assesses the effect on the likelihood of a dissemination tie when both organizations are the same level (e.g., both are local organizations). This is a homophily hypothesis, where we are testing if the same types of organizations are more likely to communicate with one another. The positive and significant parameter indicates that there is a homophily effect here.

ERGM: 3. Model2b

Model 2b shows how to test a hypothesis of differential homophily. Here, instead of one dyad term, there are three; one each for the three levels of the agency level characteristic. Thus, this model now has three homophily terms, one for local agencies, one for state, and one for national. The results suggest that the overall homophily effect is seen mainly at the local and national levels.

ERGM: 3. Model2c

¹ summary (DSmod2c)

Null Deviance: 415.9 on 300 degrees of freedom Residual Deviance: 329.7 on 293 degrees of freedom

AIC: 343.7 BIC: 369.6 (Smaller is better.)

Finally, Model 2c shows how to include the most detailed tests for homophily and heterophily. The nodemix term includes dyadic comparisons for all the possible patterns of a categorical node attribute. The base option sets a reference category for the effects, otherwise all possible effects are included (which may lead to model stability problems). Here the reference category is (1,1), indicating the ties among the local-level agencies. Note that for smaller networks and categorical attributes with a large number of values, the mixing matrix may have empty cells (as well as use up many more degrees of freedom). These can cause problems for the model estimation and interpretation.

ERGM: 4.Including Relational Terms (Network Predictors)

The third type of predictor that can be included in ERGMs is a relational predictor, where information about ties among the network members is used to predict the likelihood of the dependent variable tie.

Why R?

Software: Use R! Why R?

- vast integrated system of thousands of packages and functions
- R is free and open nature
- There is a vast R user and developer community

Packages: Several different packages:

- igraph: Network Analysis and Visualization to create, decorate, assess basics of a network.
- sand: Statistical Analysis of Network Data with R. Data sets for the book 'Statistical Analysis of Network Data with R'.
- sna: Tools for Social Network Analysis.
- statnet: Software Tools for the Statistical Analysis of Network Data.
- UserNetR: R Package provides datasets for Douglas A. Luke's "A User's Guide to Network Analysis in R" book (2015).

Other Programmes: UCINet, Structure, Pajek, Negopy, SocNetV, Gephi, StOCNET, NetMiner and many more...
